Azure Toolset Overview

High Availability & Disaster Recovery Design

Building Resilient APIs in Azure

Framing the Discipline

High Availability vs. Disaster Recovery

High Availability (HA)
Keep Running

Disaster Recovery (DR)
Recover When Stopped

Recovery Time Objective (RTO)

Recovery Point Objective (RPO)

Designing for Redundancy

Availability Zones & Region Pairs

Geographic Redundancy

Availability Zones

Region Pairs

Deployment Strategies for Resilience

Active-Active vs Active-Passive

Active-Active

Active-Passive

Keeping Data Durable & Available

Data Resilience & Replication

Azure
Storage

- Geo-redundant (GRS, RA-GRS)
- Automatic replication across regions
- Blob, file, queue, table storage

Cosmos DB

- Multi-region writes, active-active
- Tunable consistency models
- Automatic failover groups

Operational Readiness

Practice Resilience

Key Practices

- Monitoring & Alerts
- Chaos Testing / Game Days
- Runbooks & Automation

Outcomes

- Faster detection of failures
- Validated assumptions
- Predictable, repeatable recovery

Trade-Offs & Cost Lens

Balancing Cost, Complexity, and Risk

Choose the level of resilience that matches your business risk.

From Principles to Practice

Recap & Transition

- High Availability = *survive everyday failures*
- Disaster Recovery = *recovery from rare, catastrophic events*
- Tools: Zones, Region Pairs, Active-Active/Passive, Data replication, Ops Readiness, Cost Trade-offs

Resilience Strategies

Building Resilient APIs in Azure

Retry Policies

Smarter Recovery from Failures

Concepts

- Exponential Backoff – wait longer between retries
- Jitter – add randomness to avoid retry storms
- Implementation – SDKs, Polly, APIM retry policies

Why It Matters

- Prevents overwhelming a struggling service
- Improves recovery time during outages
- Reduces cascading failures

Circuit Breakers

Failing Fast to Protect the System

Concepts

- Detect repeated failures
- Block further requests while the service is unhealthy
- Allow recovery attempts after cooldown

Why It Matters

- Prevents cascading failures
- Stops clients from overwhelming a failing service
- Enables faster recovery once health improves

Throttling & Rate Limiting

Protecting Capacity

Concepts

- **Rate Limiting:** cap requests per second/minute
- **Throttling:** slow down or reject excess requests

Why It Matters

- Prevents overload and cascading failures
- Ensures fair usage across clients
- Preserves critical functionality under stress

Graceful Degradation

Preserving the Core

Concepts

- Disable or reduce non-essential features
- Serve cached or static data when live data is unavailable
- Switch to read-only-mode for critical services
- Provide clear use messaging

Why It Matters

- Keeps the core business function alive
- Minimizes user frustration and operational damage
- Buys time for recovery without total outage

Design Blueprint

Building Resilient APIs in Azure

Putting It All Together

Design Blueprint

- API Layer (Top)
- Messaging Layer (Middle)
- Data Layer (Bottom)
- Observability (Side Panel)
- Resilience Features (Top Right)

Design Blueprint: Putting It All Together

Checklist for Resilient APIs

- Implement multi-region failover
- Use autocal rules for API workloads
- Buffer traffic with Service Bus queues
- Broadcast events with Service Bus topics
- Monitor latency, error rates, and queue depth
- Trigger alerts and scale actions from metrics
- Trace requests end-to-end with App Insights
- Secure secrets with Key Vault
- Design for observability day one

Q&A
